

Error checking, functions, and loops

Lecture 03

Dr. Colin Rundel

Error Checking

stop and stopifnot

Often we want to validate user input, function arguments, or other assumptions in our code - if our assumptions are not met then we often want to report/throw an error and stop execution.

```
1 ok = FALSE
```

```
1 if (!ok)
2   stop("Things are not ok.")
```

Error in eval(expr, envir, enclos): Things are not ok.

```
1 stopifnot(ok)
```

Error: ok is not TRUE

Note - an error (like the one generated by `stop`) will prevent an RMarkdown or Quarto document from compiling

Style choices

Do stuff:

```
1  if (condition_one) {  
2  
3      ## Do stuff  
4  
5  } else if (condition_two) {  
6  
7      ## Do other stuff  
8  
9  } else if (condition_error) {  
10     stop("Condition error occurred")  
11 }
```

Do stuff (better):

```
1  # Do stuff better  
2  if (condition_error) {  
3      stop("Condition error occurred")  
4  }  
5  
6  if (condition_one) {  
7  
8      ## Do stuff  
9  
10 } else if (condition_two) {  
11  
12     ## Do other stuff  
13  
14 }
```

Exercise 1

Write a set of conditional(s) that satisfies the following requirements,

- If `x` is greater than 3 and `y` is less than or equal to 3 then print “Hello world!”
- Otherwise if `x` is greater than 3 print “!dlrow olleH”
- If `x` is less than or equal to 3 then print “Something else ...”
- `stop()` execution if `x` is odd and `y` is even and report an error, don’t print any of the text strings above.

Test out your code by trying various values of `x` and `y`.

Why errors?

R has a spectrum of output that can be provided to users,

- Printed output (i.e. `cat()`, `print()`)
- Diagnostic messages (i.e. `message()`)
- Warnings (i.e. `warning()`)
- Errors (i.e. `stop()`, `stopifnot()`)

Each of these provides outputs while also providing signals which can be interacted with programmatically (e.g. catching errors or treating warnings as errors).

Handling errors

Why use an error (or warning) vs a message vs printed / cat'ed text?

```
1 flip = function() {  
2   if (runif(1) > 0.5) stop("Heads") else "Tails"  
3 }
```

```
1 flip()
```

```
[1] "Tails"
```

```
1 x = try(flip(), silent=TRUE)  
2 x
```

```
[1] "Tails"
```

```
1 flip()
```

```
Error in flip(): Heads
```

```
1 x = try(flip(), silent=TRUE)  
2 x
```

```
[1] "Error in flip() : Heads\n"  
attr(,"class")  
[1] "try-error"  
attr(,"condition")  
<simpleError in flip(): Heads>
```

Functions

What is a function

Functions are abstractions in programming languages that allow us to modularize our code into small “self contained” units.

In general the goals of writing functions is to,

- Simplify a complex process or task into smaller sub-steps
- Allow for the reuse of code without duplication
- Improve the readability of your code
- Improve the maintainability of your code

Function Parts

In R functions are defined by *two* components: the arguments (`formals`) and the code expressions (`body`).

Functions are 1st order objects in R and have a mode of `function`. They are assigned names like other objects using `=` or `<-`.

```
1 gcd = function(x1, y1, x2 = 0, y2 = 0) {  
2   R = 6371 # Earth mean radius in km  
3  
4   # distance in km  
5   acos(sin(y1)*sin(y2) + cos(y1)*cos(y2) * cos(x2-x1)) * R  
6 }
```

```
1 typeof(gcd)
```

```
[1] "closure"
```

```
1 mode(gcd)
```

```
[1] "function"
```

We use `mode` here because there are two kinds of functions in R, `closures` and primitive functions (with type

Accessing function elements

```
1 str( formals(gcd) )
```

Dotted pair list of 4

```
$ x1: symbol  
$ y1: symbol  
$ x2: num 0  
$ y2: num 0
```

```
1 typeof( formals(gcd) )
```

```
[1] "pairlist"
```

```
1 body(gcd)
```

```
{  
    R = 6371  
    acos(sin(y1) * sin(y2) + cos(y1) *  
cos(y2) * cos(x2 - x1)) *  
    R  
}
```

```
1 typeof( body(gcd) )
```

```
[1] "language"
```

Note when using `body()` here the code we get back has had comments removed, if you want to access the full

Return values

As with most other languages, functions are most often used to process inputs and return a value as output. There are two approaches to returning values from functions in R - explicit and implicit returns.

Explicit - using one or more `return` function calls

```
1 f = function(x) {  
2   return(x * x)  
3 }  
4 f(2)
```

```
[1] 4
```

Implicit - return value of the last expression is returned.

```
1 g = function(x) {  
2   x * x  
3 }  
4 g(3)
```

```
[1] 9
```

Invisible returns

Many functions in R make use of an invisible return value

```
1 f = function(x) {  
2   print(x)  
3 }  
4  
5 y = f(1)
```

```
[1] 1
```

```
1 y
```

```
[1] 1
```

```
1 g = function(x) {  
2   invisible(x)  
3 }
```

```
1 g(2)
```

```
1 z = g(2)  
2 z
```

```
[1] 2
```

Returning multiple values

If we want a function to return more than one value we can group results using atomic vectors or lists.

```
1 f = function(x) {  
2   c(x, x^2, x^3)  
3 }  
4  
5 f(1:2)
```

```
[1] 1 2 1 4 1 8
```

```
1 g = function(x) {  
2   list(x, "hello")  
3 }  
4  
5 g(1:2)
```

```
[[1]]
```

```
[1] 1 2
```

```
[[2]]
```

```
[1] "hello"
```

More on lists next time

Argument names

When defining a function we explicitly define names for the arguments, which become variables within the scope of the function.

When calling a function we can use these names to pass arguments in an alternative order.

```
1 f = function(x, y, z) {  
2   paste0("x=", x, " y=", y, " z=", z)  
3 }
```

```
1 f(1, 2, 3)
```

```
[1] "x=1 y=2 z=3"
```

```
1 f(z=1, x=2, y=3)
```

```
[1] "x=2 y=3 z=1"
```

```
1 f(1, 2, 3, 4)
```

```
Error in f(1, 2, 3, 4): unused argument (4)
```

```
1 f(y=2, 1, 3)
```

```
[1] "x=1 y=2 z=3"
```

```
1 f(y=2, 1, x=3)
```

```
[1] "x=3 y=2 z=1"
```

```
1 f(1, 2, m=3)
```

```
Error in f(1, 2, m = 3): unused argument (m = 3)
```

Argument defaults

It is also possible to give function arguments default values, so that they don't need to be provided every time the function is called.

```
1 f = function(x, y=1, z=1) {  
2   paste0("x=", x, " y=", y, " z=", z)  
3 }
```

```
1 f(3)
```

```
[1] "x=3 y=1 z=1"
```

```
1 f(x=3)
```

```
[1] "x=3 y=1 z=1"
```

```
1 f(z=3, x=2)
```

```
[1] "x=2 y=1 z=3"
```

```
1 f(y=2, 2)
```

```
[1] "x=2 y=2 z=1"
```

```
1 f()
```

Error in f(): argument "x" is missing, with no default

Scope

R has generous scoping rules, if it can't find a variable in the current scope (e.g. a function's body) it will look for it in the next higher scope, and so on until it runs out of environments or an object with that name is found.

```
1 y = 1
2
3 f = function(x) {
4   x + y
5 }
6
7 f(3)
```

```
[1] 4
```

```
1 y = 1
2
3 g = function(x) {
4   y = 2
5   x + y
6 }
7
8 g(3)
```

```
[1] 5
```

```
1 y
```

```
[1] 1
```

Scope persistence

Additionally, variables defined within a scope only persist for the duration of that scope, and do not overwrite variables at higher scope(s).

```
1 x = 1
2 y = 1
3 z = 1
4
5 f = function() {
6   y = 2
7   g = function() {
8     z = 3
9     return(x + y + z)
10  }
11  return(g())
12 }
```

```
1 f()
```

```
[1] 6
```

```
1 c(x,y,z)
```

```
[1] 1 1 1
```

Exercise 2 - scope

What is the output of the following code? Explain why.

```
1  z = 1
2
3  f = function(x, y, z) {
4    z = x+y
5
6    g = function(m = x, n = y) {
7      m/z + n/z
8    }
9
10   z * g()
11 }
12
13 f(1, 2, x = 3)
```

Lazy evaluation

Another interesting / unique feature of R is that function arguments are lazily evaluated, which means they are only evaluated when needed.

```
1 f = function(x) {  
2   TRUE  
3 }
```

```
1 f(1)
```

```
[1] TRUE
```

```
1 f(stop("Error"))
```

```
[1] TRUE
```

```
1 g = function(x) {  
2   x  
3   TRUE  
4 }
```

```
1 g(1)
```

```
[1] TRUE
```

```
1 g(stop("Error"))
```

```
Error in g(stop("Error")): Error
```

More practical lazy evaluation

The previous example is not particularly useful, a more common use for this lazy evaluation is that this enables us define arguments as expressions of other arguments.

```
1 f = function(x, y=x+1, z=1) {  
2   x = x + z  
3   y  
4 }  
5  
6 f(x=1)
```

```
[1] 3
```

```
1 f(x=1, z=2)
```

```
[1] 4
```

Operators as functions

In R, operators are actually a special type of function - using backticks around the operator we can write them as functions.

```
1 `+`
```

```
function (e1, e2) .Primitive("+")
```

```
1 typeof(`+`)
```

```
[1] "builtin"
```

```
1 x = 4:1
```

```
2 x + 2
```

```
[1] 6 5 4 3
```

```
1 `+`(x, 2)
```

```
[1] 6 5 4 3
```

Getting Help

Prefixing any function name with a `?` will open the related help file for that function.

```
1 ?`+`  
2 ?sum
```

For functions not in the base package, you can generally see their implementation by entering the function name without parentheses (or using the `body` function).

```
1 lm
```

```
function (formula, data, subset, weights, na.action, method = "qr",  
  model = TRUE, x = FALSE, y = FALSE, qr = TRUE, singular.ok = TRUE,  
  contrasts = NULL, offset, ...)  
{  
  ret.x <- x  
  ret.y <- y  
  cl <- match.call()  
  mf <- match.call(expand.dots = FALSE)  
  m <- match(c("formula", "data", "subset", "weights", "na.action",  
    "offset"), names(mf), 0L)  
  mf <- mf[c(1L, m)]  
  mf$drop.unused.levels <- TRUE
```

Less Helpful Examples

```
1 list
```

```
function (...) .Primitive("list")
```

```
1 `[`
```

```
.Primitive("[")
```

```
1 sum
```

```
function (..., na.rm = FALSE) .Primitive("sum")
```

```
1 `+`
```

```
function (e1, e2) .Primitive("+")
```

Infix functions (operators)

We can define our own infix functions like `+` or `*`, the only requirement is that they must start and end with a `%`.

```
1 ` %nand% ` = function(x, y) {  
2   !(x & y)  
3 }
```

```
1 TRUE %nand% TRUE
```

```
[1] FALSE
```

```
1 TRUE %nand% FALSE
```

```
[1] TRUE
```

```
1 FALSE %nand% TRUE
```

```
[1] TRUE
```

```
1 FALSE %nand% FALSE
```

```
[1] TRUE
```

Replacement functions

We can also define functions that allow for ‘inplace’ modification like `attr` or `names`.

```
1 `last<-` = function(x, value) {  
2   x[length(x)] = value  
3   x  
4 }
```

```
1 x = 1:10
```

```
1 last(x) = 5L  
2 x
```

```
[1] 1 2 3 4 5 6 7 8 9 5
```

```
1 last(x) = NA  
2 x
```

```
[1] 1 2 3 4 5 6 7 8 9 NA
```

```
1 last(1)
```

Error in last(1): could not find function "last"

```
1 `modify<-` = function(x, pos, value) {  
2   x[pos] = value  
3   x  
4 }
```

```
1 x = 1:10
```

```
1 modify(x,1) = 5L  
2 x
```

```
[1] 5 2 3 4 5 6 7 8 9 10
```

```
1 modify(x, 9:10) = 1L  
2 x
```

```
[1] 5 2 3 4 5 6 7 8 1 1
```

Loops

for loops

There are the most common type of loop in R - given a vector it iterates through the elements and evaluate the code expression for each value.

```
1 is_even = function(x) {  
2   res = c()  
3  
4   for(val in x) {  
5     res = c(res, val %% 2 == 0)  
6   }  
7  
8   res  
9 }
```

```
1 is_even(1:10)
```

```
[1] FALSE  TRUE FALSE  TRUE FALSE  TRUE FALSE  TRUE FALSE  TRUE
```

```
1 is_even(seq(1,5,2))
```

```
[1] FALSE FALSE FALSE
```

while loops

This loop repeats evaluation of the code expression until the condition is **not** met (i.e. evaluates to **FALSE**)

```
1 make_seq = function(from = 1, to = 1, by = 1) {  
2   res = c(from)  
3   cur = from  
4  
5   while(cur+by <= to) {  
6     cur = cur + by  
7     res = c(res, cur)  
8   }  
9  
10  res  
11 }  
12  
13 make_seq(1, 6)
```

```
[1] 1 2 3 4 5 6
```

```
1 make_seq(1, 6, 2)
```

```
[1] 1 3 5
```

repeat loops

Equivalent to a `while(TRUE){}` loop, it repeats until a `break` statement

```
1 make_seq2 = function(from = 1, to = 1, by = 1) {  
2   res = c(from)  
3   cur = from  
4  
5   repeat {  
6     cur = cur + by  
7     if (cur > to)  
8       break  
9     res = c(res, cur)  
10  }  
11  
12  res  
13 }  
14  
15 make_seq2(1, 6)
```

```
[1] 1 2 3 4 5 6
```

```
1 make_seq2(1, 6, 2)
```

```
[1] 1 3 5
```

Special keywords - **break** and **next**

These are special actions that only work *inside* of a loop

- **break** - ends the current **loop** (inner-most)
- **next** - ends the current **iteration**

```
1 f = function(x) {  
2   res = c()  
3   for(i in x) {  
4     if (i %% 2 == 0)  
5       break  
6     res = c(res, i)  
7   }  
8   res  
9 }  
10 f(1:10)
```

```
[1] 1
```

```
1 f(c(1,1,1,2,2,3))
```

```
[1] 1 1 1
```

```
1 g = function(x) {  
2   res = c()  
3   for(i in x) {  
4     if (i %% 2 == 0)  
5       next  
6     res = c(res,i)  
7   }  
8   res  
9 }  
10 g(1:10)
```

```
[1] 1 3 5 7 9
```

```
1 g(c(1,1,1,2,2,3))
```

```
[1] 1 1 1 3
```

Some helpful functions

Often we want to use a loop across the indexes of an object and not the elements themselves. There are several useful functions to help you do this: `:`, `length`, `seq`, `seq_along`, `seq_len`, etc.

```
1 4:7
```

```
[1] 4 5 6 7
```

```
1 length(4:7)
```

```
[1] 4
```

```
1 seq(4,7)
```

```
[1] 4 5 6 7
```

```
1 seq_along(4:7)
```

```
[1] 1 2 3 4
```

```
1 seq_len(length(4:7))
```

```
[1] 1 2 3 4
```

```
1 seq(4,7,by=2)
```

```
[1] 4 6
```

Avoid using `1:length(x)`

A common loop construction you'll see in a lot of R code is using `1:length(x)` to generate a vector of index values for the vector `x`.

```
1 f = function(x) {  
2   for(i in 1:length(x)) {  
3     print(i)  
4   }  
5 }  
6  
7 f(2:1)
```

```
[1] 1
```

```
[1] 2
```

```
1 f(2)
```

```
[1] 1
```

```
1 f(integer())
```

```
[1] 1
```

```
[1] 0
```

```
1 g = function(x) {  
2   for(i in seq_along(x)) {  
3     print(i)  
4   }  
5 }  
6  
7 g(2:1)
```

```
[1] 1
```

```
[1] 2
```

```
1 g(2)
```

```
[1] 1
```

```
1 g(integer())
```

What was the problem?

```
1 length(integer())
```

```
[1] 0
```

```
1 1:length(integer())
```

```
[1] 1 0
```

```
1 seq_along(integer())
```

```
integer(0)
```

Exercise 3

Below is a vector containing all prime numbers between 2 and 100:

```
1 primes = c( 2,  3,  5,  7, 11, 13, 17, 19, 23, 29, 31, 37, 41,  
2           43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97)
```

If you were given the vector `x = c(3,4,12,19,23,51,61,63,78)`, write the R code necessary to print only the values of `x` that are *not* prime (without using subsetting or the `%in%` operator).

Your code should use *nested* loops to iterate through the vector of primes and `x`.
